SPANNING FOREST POLYNOMIALS AND THE TRANSCENDENTAL WEIGHT OF FEYNMAN GRAPHS

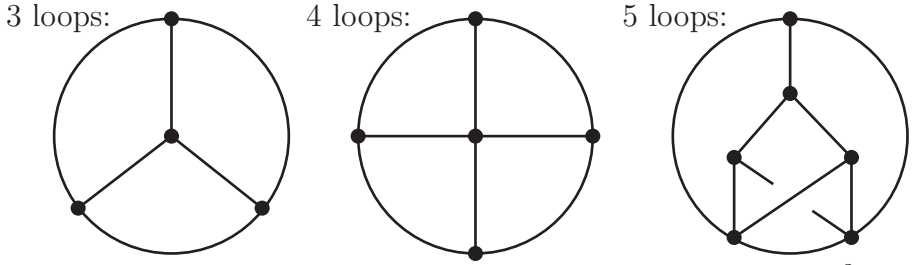
FRANCIS BROWN AND KAREN YEATS

Abstract. We give combinatorial criteria for predicting the transcendental weight of Feynman integrals of certain graphs in ϕ^4 theory. By studying spanning forest polynomials, we obtain operations on graphs which are weight-preserving, and a list of subgraphs which induce a drop in the transcendental weight.

1. Introduction

It is well-known since the work of Broadhurst and Kreimer that single-scale massless Feynman integral calculations in perturbative quantum field theories give rise empirically to multiple zeta values. In particular, there is a map from primitive graphs in ϕ^4 theory at low loop orders to linear combinations of multiple zeta values. Currently there is no way to predict this map without intensive numerical analysis.

In this paper, we consider the most simple invariant of multiple zeta values: their transcendental weight. Conjecturally, there should exist no linear relations between multiple zetas of different weights, and hence one expects there to be a grading on the ring of MZVs. On the other hand, the perturbative expansion in massless ϕ^4 theory is also graded by the number of loops. The surprising fact is that these gradings do not quite coincide. In the generic case, the transcendental weight of a graph is equal to twice its loop number minus 3. This is the case for the left and middle graphs in the examples below:



But the non-planar graph on the right has 5 loops and hence its expected weight should be $2 \times 5 - 3 = 7$; yet it has weight 6. In other

Karen Yeats is supported by an NSERC discovery grant.

words, a *weight drop* can occur. The goal of this paper is to understand combinatorially why such a weight drop arises.

Our main result describes some operations on graphs in ϕ^4 theory under which the weight is preserved. As a corollary, we produce some infinite families of graphs which are of maximal weight, and other families which have a weight drop. These two classes should contribute to ϕ^4 theory in a quite different way. In order to obtain physical predictions in practice, one must sum a large number of diagrams in a given quantum field theory at each loop order, and it is known that not all graphs contribute equally to the final sum. Indeed, some can even be discarded altogether. We hope that the notion of weight drop may shed some light on this phenomenon.

Remark 1. *It is currently not known whether all primitive graphs in ϕ^4 theory evaluate to multiple zetas or not, but the residues are always periods in the sense of* [3]*. Therefore the general conjectural picture is that there should exist a large pro-algebraic ('motivic') Galois group which acts on the set of all periods, and should in particular equip the perturbative expansion of a quantum field theory with a lot of extra structure. The notion of weight is the first non-trivial piece of information that such a theory would provide.*

1.1. **Outline.** Let G be a primitive graph in ϕ^4 theory with e_G edges. Its residue is defined by the formula

$$I_G = \int \frac{1}{\Psi_G^2} \prod_{i=1}^{e_G} d\alpha_i \delta(\alpha_\kappa = 1) \ ,$$

where α_i is the Schwinger coordinate of each edge, and I_G does not depend on the choice of κ. The graph polynomial Ψ_G is defined by

$$\Psi_G = \sum_{T \subseteq G} \prod_{e \notin T} \alpha_e$$

where T ranges over all spanning trees of G. In order to understand the integral I_G, one is naturally led [2] to consider auxilliary (or 'Dodgson') polynomials $\Psi_{G,K}^{I,J}$, where I, J, K are subsets of edges of G satisfying $|I| = |J|$. In the first part of this paper, we introduce *spanning forest polynomials* Φ_G^P associated to any partition P of a subset of vertices of G. These are sums over families of trees whose leaves contain the vertices in each partition of P. We show that every polynomial $\Psi_{G,K}^{I,J}$ can be written as a linear combination of Φ_G^P, which in particular gives a formula for the signs in $\Psi_{G,K}^{I,J}$.

Next, in §3 we study some algebraic identities between spanning forest polynomials, and give a universal formula for the graph polynomial

of any 3-vertex connected graph G in terms of the Φ_G^P. The graph polynomial for any such graph is the graph polynomial of the single graph $M(1,1,1)$ which has 6 edges, which are decorated by spanning forest polynomials. Thus to prove a statement about any 3-vertex connected graph, it suffices to prove it in this single case.

In §4 we recall some elementary properties of hyperlogarithms and give a sufficient condition for a graph to have a weight drop. This can be phrased in terms of higher graph invariants [2], which in some special cases can be computed in terms of spanning forest polynomials. Using the properties of the Φ_G^P proved previously, we show that any 2-vertex connected graph always has a weight drop. We then show that the operation of splitting a triangle and moving some of its outer edges preserves weights. These two results alone suffice to explain almost all of the known weight-drop graphs in ϕ^4 theory up to 8 loops.

In §4.6, we seek a classification of weight-preserving, or weight-dropping operations. Using the universal formula for 3-vertex connected graphs, it suffices to write down all the local minors of 3-vertex connected graphs at k edges, for small values of k, and compute their graph polynomials. From this we deduce some new families of weight-preserving operations which are not attainable by splitting triangles.

Very many thanks to S. Bloch, D. Broadhurst, D. Kreimer, and O. Schnetz for discussions and enthusiasm.

Remark 2. *One way to circumvent the transcendence conjectures for periods is to replace them with mixed Hodge structures, which was initiated in* [1]*. The question one can then ask, following (loc cit), is where in the weight filtration does the differential form defining the period sit? In this context, the weight always makes sense, but it is currently not known how to carry this out save for a few examples of graphs. Therefore, in the face of the geometric difficulties of this problem, we have instead focused on the combinatorial aspects of the weight drop, which seems to be a necessary prerequisite before trying to tackle the Hodge side. It came as a surprise to us quite how intricate this first step already is.*

1.2. **Background.** Let G be a connected multigraph, with self-loops[1] allowed. Let $E(G)$, $V(G)$ denote the set of edges and vertices of G, and let $e_G = |E(G)|$, $v_G = |V(G)|$. To each edge e of G, we associate

[1]or *tadpoles*

a Schwinger parameter α_e. The graph polynomial of G is defined by

$$\Psi_G = \sum_{T \subseteq G} \prod_{e \notin E(T)} \alpha_e \in \mathbb{Z}[\alpha_e, e \in E(G)] \ ,$$

where the sum is over all spanning trees T of G.

Definition 3. Choose an orientation on the edges of G, and for every edge e and vertex v of G, define an incidence matrix:

$$(\mathcal{E}_G)_{e,v} = \begin{cases} 1, & \text{if the edge } e \text{ begins at } v, \\ -1, & \text{if the edge } e \text{ ends at } v, \\ 0, & \text{otherwise.} \end{cases}$$

Let A be the diagonal matrix with entries α_e, for $e \in E(G)$, and set

$$\widetilde{M}_G = \left(\begin{array}{c|c} A & \mathcal{E}_G \\ \hline -\mathcal{E}_G^T & 0 \end{array} \right)$$

where the first e_G rows (resp. columns) are indexed by the set of edges of G, and the remaining v_G rows (resp. columns) are indexed by the set of vertices of G, in some order. The matrix $\widetilde{M}_G$ has zero determinant.

Definition 4. Choose any vertex of G and let M_G denote the minor obtained by deleting the corresponding row and column of $\widetilde{M}_G$.

The matrix M_G is not well-defined, but one can show that

$$\Psi_G = \det(M_G)$$

is the graph polynomial of G. This motivates the following:

Definition 5. Let I, J, K be subsets of the set of edges of G which satisfy $|I| = |J|$. Let $M_G(I,J)_K$ denote the matrix obtained from M_G by removing the rows (resp. columns) indexed by the set I (resp. J) and setting $\alpha_e = 0$ for all $e \in K$. Set

$$\Psi_{G,K}^{I,J} = \det M_G(I,J)_K \ .$$

It is clear that $\Psi_{G,\emptyset}^{\emptyset,\emptyset} = \Psi_G$. The polynomials $\Psi_{G,K}^{I,J}$ are well-defined up to sign. The following results are proved in [2].

Proposition 6. *Let $e \in E(G)$ such that $e \notin I \cup J \cup K$. Let $G \backslash e$ denote the graph obtained by deleting the edge e (and removing any isolated vertices) and let G/e denote the graph obtained by contracting e (i.e., deleting e and identifying its endpoints).*[2] *Then*

$$\begin{aligned} \Psi_{G\backslash e,K}^{I,J} &= \Psi_{G,K}^{I \cup e, J \cup e} \\ \Psi_{G/e,K}^{I,J} &= \Psi_{G,K \cup e}^{I,J} \end{aligned}$$

[2]We require that the contraction of tadpoles be zero

Since $\Psi^{I,J}_{G,K}$ is linear in the Schwinger parameters this implies that

$$\Psi^{I,J}_{G,K} = \Psi^{I,J}_{G\backslash e,K}\,\alpha_e + \Psi^{I,J}_{G/e,K}.$$

Corollary 7. *Let G, I, J, K be as above. Then*

$$\Psi^{I,J}_{G,K} = \Psi^{I',J'}_{G',\emptyset}$$

where $G' = G\backslash(I\cap J)/(K\backslash(I\cap J))$, and $I'\cap J' = \emptyset$. In other words, by passing to a minor of G, we can assume that $I\cap J = K = \emptyset$.

Now let $U \subset E(G)$ be a set of $|U| = h_1(G) = e_G - v_G + 1$ edges. Define $\mathcal{E}_G(U)$ to be a square $(v_G-1)\times(v_G-1)$ matrix obtained from $\mathcal{E}_G$ by removing the rows U, and any one column corresponding to a vertex. The matrix-tree theorem states that

$$\det \mathcal{E}_G(U) \in \{0, \pm 1\}\ ,$$

and is non-zero if and only if U is a spanning tree of G.

Proposition 8. *Suppose that $I\cap J = \emptyset$. Then*

$$\Psi^{I,J}_{G,\emptyset} = \sum_{U\subset G\backslash(I\cup J)} \prod_{u\notin U} \alpha_u \det(\mathcal{E}_G(U\cup I))\det(\mathcal{E}_G(U\cup J))$$

where U ranges over all subgraphs of $G\backslash(I\cup J)$ which have the property that $U\cup I$ and $U\cup J$ are both spanning trees in G.

The first goal of this paper is to provide combinatorial interpretations of the $\Psi^{I,J}_{G,K}$. The objects we will use to this end are spanning forests, that is, subgraphs of G which contain all vertices of G and are disjoint unions of trees.

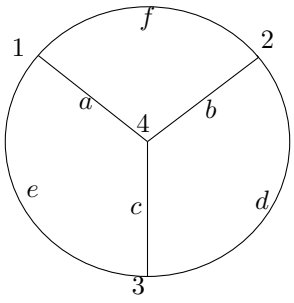
Definition 9. Let $P = P_1\cup\ldots\cup P_k$ be a set partition of a subset of the vertices of G. Define

$$\Phi^P_G = \sum_F \prod_{e\notin F} \alpha_e$$

where the sum runs over spanning forests $F = T_1\cup\ldots\cup T_k$ where each tree T_i of F contains the vertices in P_i and no other vertices of P, i.e., $V(T_i)\supseteq P_i$ and $V(T_i)\cap P_j = \emptyset$ for $j\neq i$. Trees consisting of a single vertex are permitted. Call Φ^P_G a *spanning forest polynomial* of G.

Graphically we will represent Φ^P_G by associating a colour to each part of P and drawing G with the vertices in P coloured accordingly. For

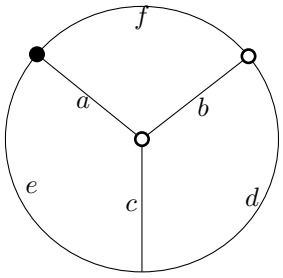
example, let G be the wheel with three spokes, labelled as illustrated.



Let $P = \{1\}, \{2, 4\}$. Then

$$\Phi_G^P = af(be + cd + ce + de)$$

Graphically we represent this



Spanning forest polynomials are well behaved under contraction and deletion. The following propositions can be most easily understood simply by drawing each Φ_G^P.

Proposition 10. *Let e be an edge variable of G and let P be a set partition of some vertices of G. Then*

$$\Phi_G^P = \begin{cases} e\Phi_{G\backslash e}^P & \text{if the ends of } e \text{ are in different parts of } P \\ e\Phi_{G\backslash e}^P + \Phi_{G/e}^{P/e} & \text{otherwise} \end{cases}$$

Where P/e is the set partition made from P by identifying the two ends of e should they appear in P.

Proof. If the ends of e are in different parts of P then the edge e must not appear in the spanning forest polynomial. Thus factoring out e is equivalent to cutting e. This leaves a spanning forest of $G\backslash e$ compatible with P. The second case follows as in the graph polynomial case. □

Proposition 11. *Let v and w be the two ends of e. Assume that v and w are not in different parts of P. Then*

$$\Phi^{P/e}_{G/e} = \begin{cases} \displaystyle\sum_{p \text{ part of } P} \sum_{\substack{p_1 \cup p_2 = p \\ p_1 \cap p_2 = \emptyset}} \Phi^{P\setminus p, p_1\cup\{v\}, p_2\cup\{w\}}_{G\setminus e} & v, w \notin P \\ \displaystyle\sum_{\substack{p_1 \cup p_2 = p \cap (V(G)\setminus\{v,w\}) \\ p_1 \cap p_2 = \emptyset}} \Phi^{P\setminus p, p_1\cup\{v\}, p_2\cup\{w\}}_{G\setminus e} & v \text{ in part } p \text{ of } P \end{cases}$$

where $P\setminus p$ means the partition consisting of the parts of P other than p, and P, q means the partition with the parts of P and with the part q.

Note that $p_1 \cup p_2$ and $p_2 \cup p_1$ are counted as two different terms of the sums provided $p_1 \neq p_2$.

Proof. Let u be the vertex $v \sim w$ in G/e.

Suppose v and w are not in P. Then u is not in P/e, so $P/e = P$ and u may belong to any tree of a spanning forest of G/e giving

$$\Phi^{P/e}_{G/e} = \sum_{p \text{ part of } P} \Phi^{P\setminus p, p\cup\{u\}}_{G/e}.$$

Any spanning forest corresponding to the partition

$$P\setminus p, p \cup \{u\}$$

in G/e, is also a spanning forest with one more tree in G. This extra tree splits $p \cup \{u\}$ into $p_1 \cup \{v\}$ and $p_2 \cup \{w\}$. Specifically,

$$\Phi^{P\setminus p, p\cup\{u\}}_{G/e} = \sum_{\substack{p_1 \cup p_2 = p \\ p_1 \cap p_2 = \emptyset}} \Phi^{P\setminus p, p_1\cup\{v\}, p_2\cup\{w\}}_{G\setminus e},$$

giving the formula for $v, w \notin P$.

Now suppose v is in part p of P, and so w is either not in P or is also in p. Then

$$P/e = P\setminus p, p' \cup \{u\}$$

where $p' = p \cap (V(G)\setminus\{v, w\})$. Any spanning forest in G/e corresponding to this set partition is again also a spanning forest with one more tree in G. This extra tree splits $p' \cup \{u\}$ into $p_1 \cup \{v\}$ and $p_2 \cup \{w\}$ where $p_1 \cup p_2 = p'$, leading, as above, to the desired sum decomposition. □

2. Signs in Dodgson polynomials

The $\Psi^{I,J}_{G,K}$ can be expanded in terms of spanning forest polynomials. This expansion provides a simple combinatorial explanation for the signs of the monomials of the $\Psi^{I,J}_{G,K}$.

In view of Corollary 7 it suffices to consider $\Psi^{I,J}_{G,K}$ with $K = \emptyset$ and $I \cap J = \emptyset$. Thus we will suppress $K = \emptyset$ from the notation.

Proposition 12. *Let I and J be sets of edges of G with $|I| = |J|$ and $I \cap J = \varnothing$. Then we can write*

$$\Psi^{I,J}_G = \sum_k f_k \Phi^{P_k}_G$$

where the sum runs over partitions of $V(I \cup J)$ and $f_k \in \{-1, 0, 1\}$.

Proof. Take a particular monomial m in $\Psi^{I,J}_G$. Let M denote the set of edges in m, and N the complementary set of edges in $G\backslash(I \cup J)$. We know that $N \cup I$ and $N \cup J$ are spanning trees in G, and so N is a forest. The coefficient in front of m is obtained by setting all Schwinger parameters in N to zero, and taking the coefficient of all remaining parameters M. In other words, the coefficient of m is exactly

$$\Psi^{I,J}_{G\backslash M/N}$$

which by Proposition 8 is given by

$$\det(\mathcal{E}_{G\backslash M/N}(I)) \det(\mathcal{E}_{G\backslash M/N}(J)) \in \{0, \pm 1\} \ .$$

This vanishes if I and J are not spanning trees in $G\backslash M/N$. The only information of m which remains in $G\backslash M/N$ is which end points of edges of I and J belong to the same tree of N. Thus every monomial which gives the same set partition of $V(I \cup J)$ has the same sign, and every monomial corresponds to some such set partition. □

Example 13. One simple example is the case where I and J each consist of a single edge with a common vertex v. Let u and w be the other two end points. The only set partition with a nonzero coefficient in this case is $\{v\}\{u, w\}$. Graphically, if

$G =$ 
then $\Psi^{1,2}_G = \pm$ 
Definition 14. Let I, J be two subsets of edges of G with $|I| = |J|$ and let P be a partition of $V(I \cup J)$. Let I_P (resp. J_P, $\big(I \cup J\big)_P$) denote the graph obtained from the subgraph I (resp. J, $I \cup J$) by identifying vertices which lie in the same partition. If the edges of G are oriented, or are ordered, then the graphs I_P, J_P, $\big(I \cup J\big)_P$ inherit these extra structures also. If the vertices of G are ordered then the graphs I_P, J_P, $\big(I \cup J\big)_P$ inherit this structure by using the first vertex in each part to give the order.

The proof of the previous proposition shows that $f_k = \Psi^{I,J}_{(I\cup J)_P}$. The coefficient is non-zero precisely when both I_P and J_P are trees, and have exactly one vertex of every colour.

Definition 15. Let T be a rooted tree, with edges labelled from $\{1,\dots,n\}$ and non-root vertices labelled $\{1,\dots,n\}$. Choose an orientation on its edges. We define a number by constructing a bijection

$$\phi : E(T) \to V(T)$$

and a map $s : E(T) \to \{\pm 1\}$ as follows. To each $e \in E(T)$, $\phi(e)$ associates the vertex meeting e which is furthest from the root, and $s(e)$ is $+1$ if $\phi(e)$ is the endpoint of the oriented edge e, and -1 if it is the initial point. Define the sign of the (oriented, numbered) tree T to be:

$$\varepsilon(T) = \operatorname{sgn}(\phi) \prod_{e\in E(T)} s(e) \ .$$

Proposition 16. *Choose an ordering on the edges and vertices of G and an orientation of its edges. Let I, J be subsets of edges of G and P a partition on $V(I \cup J)$. Then*

$$\Psi^{I,J}_{(I\cup J)_P} = \varepsilon(I_P)\varepsilon(J_P).$$

Proof. From the proof of proposition 12, we have

$$\Psi^{I,J}_{(I\cup J)_P} = \det(\mathcal{E}_{(I\cup J)_P}(I_P)) \det(\mathcal{E}_{(I\cup J)_P}(J_P)).$$

This vanishes if I_P and J_P are not both trees. In the case where they are, an inspection of the matrices $\mathcal{E}_{(I\cup J)_P}(I_P)$ shows that its determinant is exactly $\varepsilon(I_P)$. The choice of vertex v to remove in $\Psi^{I,J}_{(I\cup J)_P}$ becomes the choice of roots for I_P and J_P by taking as roots the vertices of I_P and J_P which correspond to the part of v. □

As a corollary we can easily understand how the sign changes under simple transformations of P.

Let I and J be sets of edges of G with $|I| = |J|$ and $I \cap J = \emptyset$. Let

$$\Psi^{I,J}_G = \sum_k f_k \Phi^{P_k}_G$$

be as in Proposition 12. Suppose P_i and P_j are set partitions appearing in the sum which agree on $V(I)$.

Without loss of generality, order the vertices so that all of $V(I)$ comes before $V(J)$. Then the matrices on the I side are identical for P_i and P_j and we have an order of the parts of P_i and P_j on J (coming from the vertex order on I) which gives the vertex order on J_{P_i} and J_{P_j}.

Corollary 17. *Suppose P_i and P_j differ on V_J by a transposition of two vertices in the same tree of J. Then*

$$f_i = -f_j$$

Proof. The choice of a root r in J_P determines a choice of root in each tree of J recursively. To see this, first take each vertex which reduces to r as a root in its tree. Next, for each tree which under P has a vertex v which is identified with a vertex in an already rooted tree of J, take v as the root. Continue until all trees are rooted. Since only the vertex of each edge which is furthest from r in J_P contributes to the sign, we can compute the sign tree by tree and multiply, using the order of the vertices given by the order of the parts on J.

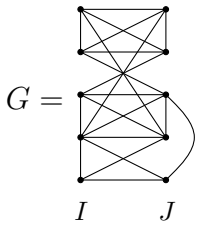
Let v and w be the two transposed vertices in the statement above. If neither are a root, then the permutation ϕ from Definition 15, taken tree by tree, is composed with a transposition, changing the sign. If it is not possible to choose the root of J_P so that this occurs, then v and w must be the only vertices in their tree of J. In this case switching the parts of v and w has the same effect as switching the orientation of the edge between them, again changing the sign. □

Corollary 18. *Suppose P_i and P_j differ on V_J by one vertex having switched parts. Then*

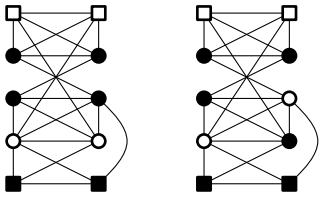
$$f_i = f_j$$

Proof. Let v be the vertex which changes part. Let F be the forest of two trees given by J with the identifications of P_i or P_j except that v is not identified with its part-mates. As in the previous corollary, we can compute the sign at the level of F. By taking the root of J_{P_i} and J_{P_j} to be in the tree of F which does not contain v we get v to be the root of the other tree of F. Thus, by the definition of ϕ, v does not contribute to the sign. □

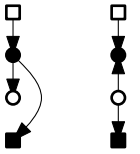
Example 19. Let



with the three vertical edges on the left being I and the three vertical edges on the left being J. Consider the two set partitions



which agree on the ends of I and differ by a transposition on the ends of J. Orient the edges of I and J downwards. The graphs J_{P_1}, J_{P_2} are



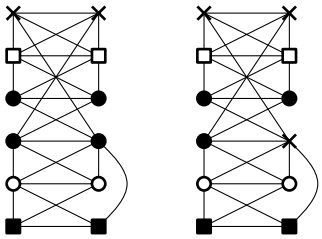
so with the filled square as the removed vertex

$$\mathcal{E}_{(I\cup J)_{P_1}}(I_{P_1}) = \begin{bmatrix} 1 & -1 & 0 \\ 0 & 1 & -1 \\ 0 & 1 & 0 \end{bmatrix} \text{ and } \mathcal{E}_{(I\cup J)_{P_2}}(I_{P_2}) = \begin{bmatrix} 1 & -1 & 0 \\ 0 & -1 & 1 \\ 0 & 0 & 1 \end{bmatrix}$$

Calculate $\det(\mathcal{E}_{(I\cup J)_{P_1}}(I_{P_1})) = -1$ and $\det(\mathcal{E}_{(I\cup J)_{P_2}}(I_{P_2})) = 1$ as expected from Proposition 17.

Example 20. Let

$G =$ 
with the four vertical edges on the left being I and the four vertical edges on the left being J. Consider the two set partitions



which agree on the ends of I and differ by a single vertex having changed colour on the ends of J. Orient the edges of I and J downwards. With the empty square as the removed vertex

$$\mathcal{E}_{(I\cup J)_{P_1}}(I_{P_1}) = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 1 & -1 & 0 \\ 0 & 1 & 0 & -1 \end{bmatrix} \text{ and } \mathcal{E}_{(I\cup J)_{P_2}}(I_{P_2}) = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 1 & 0 & -1 & 0 \\ 1 & 0 & 0 & -1 \end{bmatrix}$$

Both determinants are -1 as expected from Proposition 18.

3. Identities

Spanning forest polynomials give a nice way to look at graph polynomial identities. To illustrate this we will first recast useful known identities and then prove a new identity which generalizes results of [2].

We say a graph is *two vertex reducible* if we can remove two vertices of the graph, and the adjoining edges, and the resulting graph is disconnected.

Let G_1 and G_2 be two graphs. Let e_1 be an edge of G_1 and e_2 an edge of G_2. Then define a *two-vertex join* of G_1 and G_2 to be the graph resulting from identifying e_1 and e_2 and then cutting the new edge. Given e_1 and e_2 there are two ways to do this identification. However, this ambiguity is of little interest to us because the period of the graph does not depend on it [4], nor does the graph polynomial.

Proposition 21. *Let G be a two-vertex join as above with v_1 and v_2 the join vertices. Suppose that edges $i, j, k, l \in G$ are such that $i, j \in G_1$ and $k, l \in G_2$. Then*

$$\begin{aligned} \Psi_G &= \Phi_{G_1\setminus e_1}^{\{v_1\},\{v_2\}} \Phi_{G_2\setminus e_2} + \Phi_{G_1\setminus e_1} \Phi_{G_2\setminus e_2}^{\{v_1\},\{v_2\}} \\ \Psi_G^{ij,kl} &= 0 \\ \Psi_G^{ik,jl} &= \Psi_G^{il,jk}. \end{aligned}$$

Proof. The first identity holds because every spanning tree of G either connects v_1 and v_2 on the G_1 side or on the G_2 side. In either case the remaining side has a forest of two trees, one connected to v_1 the other to v_2. Pairings of such a forest with a spanning tree on the other side give all spanning trees of G.

Consider $\Psi^{ij,kl}$. Any monomial appearing in this polynomial is a monomial in $\Psi_{G/\{i,j\}}$ and in $\Psi_{G/\{k,l\}}$. Thus any spanning forest polynomial appearing in the expansion of $\Psi^{ij,kl}$ comes from a partition with exactly three parts and all three parts are represented among the end points of i and j as well as among the end points of k and l. This

means there are three trees which connect G_1 to G_2 in G. However G_1 and G_2 join at only two vertices. This is a contradiction and so there are no such monomials.

Then $\Psi^{ik,jl} = \Psi^{il,jk}$ by the Plücker identity [2]

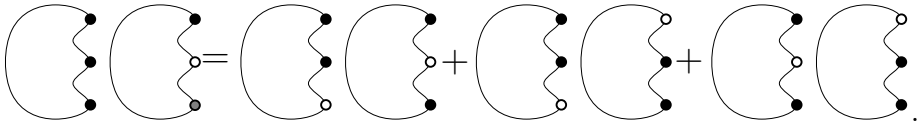
$$\Psi_G^{ij,kl} - \Psi_G^{ik,jl} + \Psi_G^{il,jk} = 0.$$

□

Proposition 22. *Let u, v, and w be vertices of a graph G. Then*

$$\begin{aligned}&\Phi_G^{\{u,v,w\}}\Phi_G^{\{u\},\{v\},\{w\}}\\ &= \Phi_G^{\{u,v\},\{w\}}\Phi_G^{\{u,w\},\{v\}} + \Phi_G^{\{u,v\},\{w\}}\Phi_G^{\{u\},\{v,w\}} + \Phi_G^{\{u,w\},\{v\}}\Phi_G^{\{u\},\{v,w\}}\end{aligned}$$

Graphically,



This identity is essentially the so-called Dodgson identity in this context.

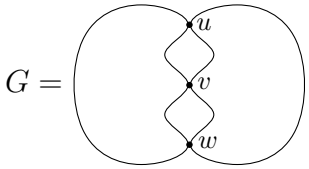
Proof. Use the Dodgson identity,

$$\begin{aligned}&\det(M_G(12,12))\det(M_G)\\ &= \det(M_G(1,1))\det(M_G(2,2)) - \det(M_G(1,2))\det(M_G(2,1))\end{aligned}$$

along with Proposition 6 and Example 13. □

The graphical formulation suggests interpreting this proposition as a result about transferring an extra edge from any term in the left hand factor of the left hand side to the right hand factor of the left hand side, thus cutting a spanning tree into two in the left hand factor and joining two of the three trees together in the right hand factor. The proposition says that transferring an edge in this way results in two spanning forests with exactly two trees in all possible ways. However carrying this idea through to a proof is delicate as there are many ways the cutting can be done and many ways to build any particular forest of two trees with an extra edge. It isn't obvious a priori that the counting works out and the authors are not aware of a proof along these lines, though one must surely exist.

Theorem 23. *Let*



be a graph which is three vertex reducible at vertices $\{u, v, w\}$. *Let* G' *and* G'' *be the two halves of* G *when separated at* u, v, *and* w. *Let*

$$\begin{aligned} f_1 &= \Phi_{G'}^{\{u\},\{v,w\}} & g_1 &= \Phi_{G''}^{\{u\},\{v,w\}} \\ f_2 &= \Phi_{G'}^{\{v\},\{u,w\}} & g_2 &= \Phi_{G''}^{\{v\},\{u,w\}} \\ f_3 &= \Phi_{G'}^{\{w\},\{u,v\}} & g_3 &= \Phi_{G''}^{\{w\},\{u,v\}} \\ f &= \Psi_{G'} = \Phi_{G'}^{\{u,v,w\}} & g &= \Psi_{G''} = \Phi_{G''}^{\{u,v,w\}} \\ \widetilde{f} &= \Phi_{G'}^{\{u\},\{v\},\{w\}} & \widetilde{g} &= \Phi_{G''}^{\{u\},\{v\},\{w\}} \end{aligned}$$

Then

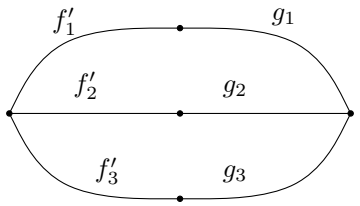
$$\begin{aligned} & f^{\deg(g)+1} g \Psi_G \\ &= \Big(f_1'f_2' + f_1'f_3' + f_2'f_3' + f_1'g_2 + f_1'g_3 + f_2'g_1 \\ &\qquad + f_2'g_3 + f_3'g_1 + f_3'g_2 + g_1g_2 + g_1g_3 + g_2g_3 \Big) \Big|_{\alpha_1,\alpha_2,\ldots,f\beta_1,f\beta_2,\ldots} \end{aligned}$$

where $f_i' = f_i g$, $\alpha_1, \cdots$ *are the variables for the edges of* G' *and* $\beta_1, \cdots$ *are the variables for the edges of* G''.

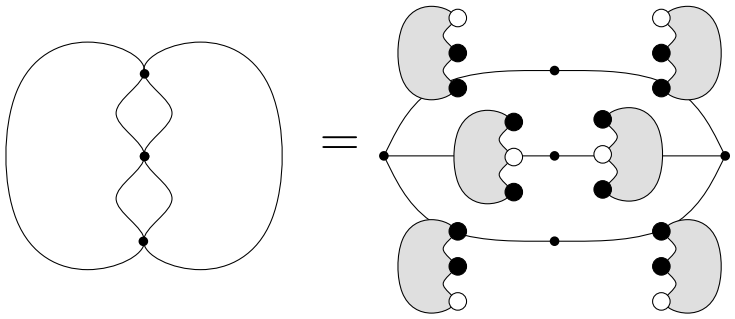
Note that the piece in parentheses of the expression for Ψ_G,

$$f_1'f_2'+f_1'f_3'+f_2'f_3'+f_1'g_2+f_1'g_3+f_2'g_1+f_2'g_3+f_3'g_1+f_3'g_2+g_1g_2+g_1g_3+g_2g_3$$

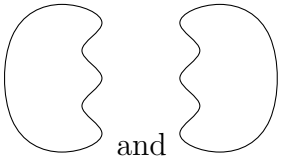
is itself the graph polynomial of the following graph with the indicated polynomials as edge variables



Graphically, then, we can represent the theorem as



Note however that this picture does not capture all the details of the theorem as it does not indicate the scalings by powers of



and .

Proof. Any tree contributing to a term of Ψ_G breaks up uniquely into a spanning forest of G' and a spanning forest of G''. A pair of a spanning forest of G' and a spanning forest of G'' give a tree of G precisely when each tree of each forest contains at least one of u, v, and w and when there is exactly one path between each pair of u, v, and w using both spanning forests. Thus

$$\Psi_G = \widetilde{f}g + f_1g_2 + f_1g_3 + f_2g_1 + f_2g_3 + f_3g_1 + f_3g_2 + f\widetilde{g}$$

Let $n = \deg g$. Note that $\deg g_i = n+1$ and $\deg \widetilde{g} = n+2$. Multiplying by f^{n+1} and using Proposition 22 we get

$$\begin{aligned} f^{n+1}\Psi_G =& f^n(f_1f_2g + f_1f_3g + f_2f_3g) \\ &+ f^{n+1}(f_1g_2 + f_1g_3 + f_2g_1 + f_2g_3 + f_3g_1 + f_3g_2) + f^{n+2}\widetilde{g} \end{aligned}$$

Let $\alpha_1, \ldots,$ be the edges of G' and let $\beta_1, \ldots,$ be the edges of G''. Scale the edges of G'' by f giving

$$\begin{aligned} f^{n+1}\Psi_G = \Big(& f_1f_2g + f_1f_3g + f_2f_3g + f_1g_2 + f_1g_3 + f_2g_1 \\ &+ f_2g_3 + f_3g_1 + f_3g_2 + \widetilde{g}\Big)\Big|_{\alpha_1,\alpha_2,\ldots,f\beta_1,f\beta_2,\ldots} \end{aligned}$$

Next multiply by g and use Proposition 22

$$\begin{aligned} & f^{n+1} g \Psi_G \\ & = \Big(f_1' f_2' + f_1' f_3' + f_2' f_3' + f_1' g_2 + f_1' g_3 + f_2' g_1 \\ & \qquad + f_2' g_3 + f_3' g_1 + f_3' g_2 + g_1 g_2 + g_1 g_3 + g_2 g_3 \Big) \Big|_{\alpha_1, \alpha_2, \ldots, f\beta_1, f\beta_2, \ldots} \end{aligned}$$

where $f_i' = f_i g$, which is the desired result. □

4. Weight drop in Feynman graphs

4.1. **Hyperlogarithms.** Let $\sigma_0 = 0$, and let $\sigma_1, \ldots, \sigma_N$ denote N distinct points in $\mathbb{C}^*$. Let $\Sigma = \{\sigma_0, \ldots, \sigma_N\}$, and let

$$Y = \mathbb{C} \backslash \Sigma \ .$$

Let $A = \{\mathsf{x}_0, \ldots, \mathsf{x}_N\}$ denote an alphabet with $N+1$ letters, and let A^* denote the free non-commutative monoid on X, which consists of the set of all words w in the alphabet A and the empty word e. Let $\mathbb{C}\langle\langle A \rangle\rangle$ denote the ring of non-commutative formal power series in A, equipped with the concatenation product. For any element $S \in \mathbb{C}\langle\langle A \rangle\rangle$, let S_w denote the coefficient of w in S, i.e.,

$$S = \sum_{w \in A^*} S_w w \quad , \quad S_w \in \mathbb{C} \ .$$

Consider the trivial bundle $E = Y \times \mathbb{C}\langle\langle A \rangle\rangle$ over Y, and consider the following one-form on Y:

$$\Omega(z) = \Big(\sum_{i=0}^{N} \mathsf{x}_i \frac{dz}{z - \sigma_i} \Big)$$

Since $d\Omega(z) = \Omega(z) \wedge \Omega(z) = 0$ this defines a flat connection on E. There is a unique multivalued section $L : Y \to E$ which satisfies:

$$\begin{aligned} dL(z) &= \Omega(z) L(z) \ , \\ L(z) &\sim \exp(\mathsf{x}_0 \log z) \end{aligned} \tag{1}$$

where the notation $L(z) \sim \exp(\mathsf{x}_0 \log z)$ means that there exists a function $h(z)$ holomorphic in the neighbourhood of the origin, such that $h(0) = 1$ and $L(z) = h(z) \exp(\mathsf{x}_0 \log z)$ for z near 0. If $w = \mathsf{x}_{i_1} \ldots \mathsf{x}_{i_r}$

where $i_r \neq 0$, then one can show that the coefficient $L_w(z)$ of $L(z)$ is an iterated integral:

$$L_w(z) = \int_{0 \leq t_r \leq t_{r-1} \leq \ldots \leq t_1 \leq z} \frac{dt_r}{t_r - \sigma_{i_r}} \ldots \frac{dt_2}{t_2 - \sigma_{i_2}} \frac{dt_1}{t_1 - \sigma_{i_1}}$$

for $z \in \mathbb{R}$ in a neighbourhood of 0. The equations (1) are equivalent to the following system of differential equations on the coefficients $L_w(z)$, and determine them uniquely:

$$\begin{aligned} \frac{\partial}{\partial z} L_{\mathrm{x}_i w}(z) &= \frac{1}{z - \sigma_i} L_w(z) \text{ for } i = 0, \ldots, N \\ L_{\mathrm{x}_0^n}(z) &= \frac{1}{n!} \log^n(z) \\ L_w(z) &\sim 0 \text{ as } z \to 0 \text{ if } w \neq x_0^n \end{aligned}$$

Lemma 24. *We deduce the following indefinite integrals (with constants of integration omitted), where the denominators are of degree at most 2 in z:*

i). $\displaystyle\int \frac{L_w(z)}{z - \sigma_i} dz = L_{\mathrm{x}_i w}(z)$

ii). $\displaystyle\int \frac{L_w(z)}{(z - \sigma_i)(z - \sigma_j)} dz = \frac{1}{\sigma_i - \sigma_j} \Big(L_{\mathrm{x}_i w}(z) - L_{\mathrm{x}_j w}(z) \Big)$

iii). $\displaystyle\int L_{\mathrm{x}_{i_1} \ldots \mathrm{x}_{i_n}}(z) dz = \sum_{k=1}^{n} (-1)^{k-1} (z - \sigma_{i_k}) L_{\mathrm{x}_{i_{k+1}} \ldots \mathrm{x}_{i_n}}(z)$

iv). $\displaystyle\int \frac{L_{\mathrm{x}_i^r \mathrm{x}_j w}(z)}{(z - \sigma_i)^2} dz = \frac{1}{z - \sigma_i} \Big(\sum_{k=1}^{r} (-1)^{k+1} L_{\mathrm{x}_i^{r-k} \mathrm{x}_j w} \Big) + \frac{1}{\sigma_i - \sigma_j} \Big(L_{\mathrm{x}_i w}(z) - L_{x_j w}(z) \Big)$

where $i \neq j$, $r \geq 0$, and $i_1, \ldots, i_n$ are any indices in $\{0, \ldots, n\}$.

Proof. (i) and (ii) follow from the definition of the functions $L_w(z)$ and partial fractions. (iii) and (iv) follow by integration by parts and induction. □

Definition 25. Let $\mathcal{L}$ denote the $\mathbb{Q}$-vector space spanned by the multi-valued functions $L_w(z)$, for $w \in A^*$ (which can be shown to be linearly independent). It is graded by the weight, where the weight $|w|$ of a word $w \in A^*$ is the number of letters in w. We write $\mathcal{L} = \bigoplus_{n \geq 0} \mathrm{gr}_n^W \mathcal{L}$, and $W_k \mathcal{L} = \bigoplus_{0 \leq n \leq k} \mathrm{gr}_n^W \mathcal{L}$.

It turns out that $\mathcal{L}$ is closed under multiplication (by the shuffle product formula), and is in fact a graded Hopf algebra. The various cases of the previous lemma are summarized in the following corollary.

Corollary 26. *Let $F(z)$ be an element of $\mathrm{gr}_k^W\mathcal{L}$ of weight k, and let $P(z) = az^2+bz+c$ be a polynomial in z of degree at most 2 with zeros in Σ. Let $\Delta(P) = b^2-4ac$ denote the discriminant of $P(z)$. Then*

$$\int \frac{F(z)}{P(z)}dz \in \begin{cases} \frac{1}{\sqrt{\Delta(P)}}\mathrm{gr}_{k+1}^W\mathcal{L} & \text{if } \Delta(P)\neq 0, \qquad (\text{“no weight drop”}) \\ W_k\mathcal{L} & \text{if } \Delta(P)=0. \qquad (\text{“weight drop”}) \end{cases}$$

Note that in the case when a weight drop occurs, the primitive is not necessarily pure as there may be mixing of weights.

Proof. The case $\Delta(P)=0$ corresponds to (iii) and (iv) in the previous lemma, and the remaining cases (i) and (ii) correspond to $\Delta(P)\neq 0$. □

4.2. **Initial integrations.** One can use the algebras $\mathcal{L}$ to integrate out the first few variables in a Feynman integral. Let G be a primitive-divergent graph, and choose an order on its edges. Consider the residue:

$$I_G = \int_{[0,\infty]^{e_G}} \frac{1}{\Psi_G^2}\prod_{i=1}^{e_G} d\alpha_i\,\delta(\alpha_{e_G}=1)$$

We can successively integrate out the variables $\alpha_1,\ldots,\alpha_5$ using lemma 24. Dropping the δs from the notation, this gives [2]:

$$I_G^1 = \int \frac{1}{\Psi_G^{1,1}\Psi_{G,1}}\prod_{i=2}^{e_G} d\alpha_i$$

$$I_G^2 = \int \frac{\log\Psi_{G,2}^{1,1}+\log\Psi_{G,1}^{2,2}-\log\Psi_G^{12,12}-\log\Psi_{G,12}}{(\Psi_G^{1,2})^2}\prod_{i=3}^{e_G} d\alpha_i$$

$$I_G^3 = \int \Big(\frac{\Psi_G^{123,123}\log\Psi_G^{123,123}}{\Psi_G^{12,13}\Psi_G^{12,23}\Psi_G^{13,23}} - \frac{\Psi_{G,123}\log\Psi_{G,123}}{\Psi_{G,1}^{2,3}\Psi_{G,2}^{1,3}\Psi_{G,3}^{1,2}} + \sum_{\{i,j,k\}}\frac{\Psi_{G,jk}^{i}\log\Psi_{G,jk}^{i}}{\Psi_G^{ij,ik}\Psi_{G,j}^{i,k}\Psi_{G,k}^{i,j}} - \frac{\Psi_{G,k}^{ij}\log\Psi_{G,k}^{ij}}{\Psi_G^{ij,ik}\Psi_G^{ij,jk}\Psi_{G,k}^{i,j}}\Big)\prod_{i=4}^{e_G} d\alpha_i$$

where the sum runs over permutations of $\{1,2,3\}$ and so there are 8 terms in the last integral. Continuing in a similar way and exploiting the many algebraic relations between the polynomials $\Psi_K^{I,J}$ [2], one verifies that:

$$(2)\quad I_G^4 = \int \Big(\frac{A}{\Psi_G^{12,34}\Psi_G^{13,24}} + \frac{B}{\Psi_G^{14,23}\Psi_G^{13,24}} + \frac{C}{\Psi_G^{12,34}\Psi_G^{13,24}}\Big)\prod_{i=5}^{e_G} d\alpha_i$$

$$(3)\quad I_G^5 = \int \frac{F}{{}^5\Psi_G(1,2,3,4,5)}\prod_{i=6}^{e_G} d\alpha_i\ .$$

where A, B, C are hyperlogarithms of weight 2, and F is a hyperlogarithm of weight 3 with singularities in $\{\Psi^{I,J}_{G,K} = 0\}$ where $I \cup J \cup K = \{1,2,3,4,5\}$. The 5-invariant ${}^5\Psi(1,2,3,4,5)$ is defined as follows:

Definition 27. The 5-invariant of any 5 edges i,j,k,l,m in G is:

$${}^5\Psi_G(i,j,k,l,m) = \pm \det \begin{pmatrix} \Psi^{ij,kl}_{G,m} & \Psi^{ijm,klm}_{G} \\ \Psi^{ik,jl}_{G,m} & \Psi^{ikm,jlm}_{G} \end{pmatrix}$$

It is well-defined, i.e., permuting i,j,k,l,m in the above only changes the sign of the determinant.

4.3. **Denominator reduction.** The denominator reduction is an algorithm for computing the denominators at successive stages of integration using Corollary 26.

Definition 28. Let G be a primitive-divergent graph and choose an ordering on its set of edges. Let $D_5 = {}^5\Psi_G(1,2,3,4,5)$. Let $n \geq 5$, and suppose inductively that D_n factorizes into a product of linear factors in α_{n+1}, i.e., $D_n = (a\alpha_{n+1} + b)(c\alpha_{n+1} + d)$. Then we define

$$D_{n+1} = \sqrt{\Delta(D_n)} = \pm(ad - bc) \ ,$$

where the discriminant Δ is taken with respect to α_{n+1}. A graph G for which the polynomials D_n can be defined for all n is called *denominator-reducible*. If for some n, D_n is a perfect square in α_{n+1}, then D_{n+1}, and all D_m for $m \geq n+1$ are identically 0. In this case, we say that G has a *weight drop*. Otherwise, G is *non-weight drop*.

Remark 29. *The interpretation of D_n as a denominator proves that D_n does not depend on the chosen order of variables up to that point. We will frequently use the notation*

$${}^n\Psi_G(e_1, \ldots, e_n) \qquad n \geq 5,$$

to denote the denominator D_n of the graph G after reducing with respect to the edges $e_1, \ldots, e_n$.

We have the following rather naive definition of the transcendental weight of a period:

Definition 30. Let P, Q be polynomials in $\overline{\mathbb{Q}}[x_1, \ldots, x_n]$ and consider an absolutely convergent period of the form:

$$I = \int_{[0,\infty]^n} \frac{P(x_1, \ldots, x_n)}{Q(x_1, \ldots, x_n)} dx_1 \ldots dx_n \ .$$

We say that such a period has weight at most n if it can be written as a sum of convergent period integrals as above with at most n integrations.[3] This defines a filtration on the set of these periods.

The definition of weight as given above is compatible with the weight filtration on the elements $L_w(z)$ of $\mathcal{L}$. It is satisfactory for periods of mixed Tate motives, and in particular should give back the usual notion of weight for multiple zeta values, however, in the general case it is a little simplistic; as remarked earlier, a more sophisticated approach to the weight is to view I as a period of a mixed Hodge structure. It is remarked in [2] that the arguments we give in this paper do in fact prove an analogous result on the weights in the Hodge-theoretic sense.

It follows from the computations of I^4_G above that I can be written as a $2 + e_G - 5 = e_G - 3$ fold integral (each term A, B, C is of weight 2 and can therefore be written as a 2-fold integral), and there remain $e_G - 5$ Schwinger parameters to integrate out owing to the $\delta(\alpha_{e_G} - 1)$ term. It follows that the weight of I_G is at most $e_G - 3$.

Theorem 31. [2] *Suppose that G is primitively divergent as above and has a weight drop at the n^{th} stage of its denominator reduction. If furthermore G is linearly reducible up to the n^{th} point, then the weight of I_G is at most $e_G - 4$.*

The linear reducibility condition guarantees that the integrands in the integration process can indeed be written as hyperlogarithms (i.e., they are multivalued functions on a Zariski open subset of projective space and have global unipotent monodromy). The previous calculations make it clear that every graph G is linearly reducible up to the 5^{th} stage. Sufficient conditions for linear reducibility are given in [2].

Remark 32. *If G is linearly reducible and has no weight drop, then the expected transcendental weight of I_G is $e_G - 3$.*

The purpose of this paper is to investigate the *combinatorial* conditions under which a weight drop (defined by the vanishing of a denominator D_n) occurs.

[3] This corresponds to the fact that the mixed Hodge structure of a complex of open affine varieties of dimension at most n has weights contained in $[0, 2n]$.

4.4. **Weight-preserving operations.** Let

$G =$ 
where the circled vertices indicate where the explicitly drawn edges attach to the rest of the graph, which is left undrawn to avoid clutter. Let K be the rest of the graph, $K = G\backslash\{1,2,3,4,5\}$. Let

$H = G\backslash\{2\} =$ 
Proposition 33.

$$\begin{aligned} {}^5\Psi_G(1,2,3,4,5) &= \pm\Psi_H^{13,45}\Psi_{H,13}^{4,5} \\ &= \pm\left(\Phi_K^{\{A,B\},\{C,D\}} - \Phi_K^{\{A,C\},\{B,D\}}\right)\Phi_K^{\{A,D\},\{B\},\{C\}} \end{aligned}$$

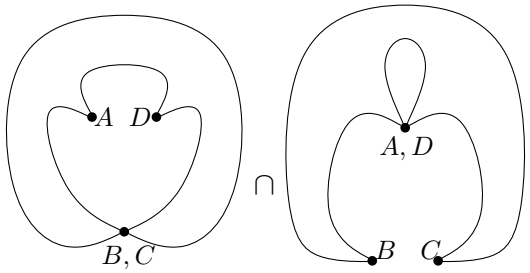
Proof. Since 123 forms a triangle, we have

$${}^5\Psi_G(1,2,3,4,5) = \pm\Psi_G^{123,245}\Psi_{G,2}^{14,35}.$$

Drawing K as a blob and using $\cap$ to indicate the polynomial formed of terms common to each argument with signs as in Proposition 12, we have

$\Psi_{G,2}^{14,35} =$ 
$$= \pm\Phi_K^{\{A,D\},\{B\},\{C\}}$$

$$\Psi_G^{123,245} = \quad \cap$$

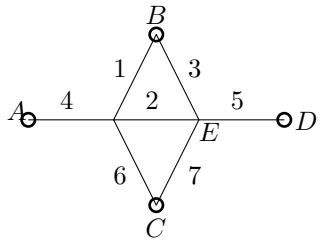


$$= \pm \left(\Phi_K^{\{A,B\},\{C,D\}} - \Phi_K^{\{A,C\},\{B,D\}} \right)$$

$\Psi_{H,13}^{4,5}$ gives the same intersection of blobs as $\Psi_{G,2}^{14,35}$ and $\Psi_H^{13,45}$ gives the same intersection of blobs as $\Psi_G^{123,245}$. The result follows. □

Consider a 'double triangle':

$G' =$



Let K again be the rest of the graph, $K = G' \backslash \{1,2,3,4,5,6,7\}$. Note that $H = (G' \backslash \{3,7\}/2)\,|_{6 \leftrightarrow 3}$.

Proposition 34. *The denominator D_7 after reducing G' with respect to the seven edges $1-7$ indicated above, is given by*

$$\begin{aligned} D_7(G') &= \pm \Psi_H^{13,45} \Psi_{H,13}^{4,5} \\ &= \pm \left(\Phi_K^{\{A,B\},\{C,D\}} - \Phi_K^{\{A,C\},\{B,D\}} \right) \Phi_K^{\{A,D\},\{B\},\{C\}} \end{aligned}$$

Proof. By Proposition 33 applied to edges $1,3,2,4,6$ we know that

$${}^5\Psi_{G'}(1,2,3,4,6) = \pm \Phi_{K \cup \{5,7\}}^{\{A,C\},\{B\},\{E\}} \left(\Phi_{K \cup \{5,7\}}^{\{A,B\},\{C,E\}} - \Phi_{K \cup \{5,7\}}^{\{A,E\},\{B,C\}} \right)$$

Notice that in the partition $\{A,C\},\{B\},\{E\}$ the two ends of edge 7 are in different parts. Thus, by Proposition 10

$$\Phi_{K \cup \{5,7\}}^{\{A,C\},\{B\},\{E\}} = \alpha_7 \Phi_{K \cup 5}^{\{A,C\},\{B\},\{E\}}.$$

This removes one term in the discriminant so we can easily apply a denominator reduction with respect to the edge 7. We deduce that

$$ {}^{6}\Psi_{G'}(1,2,3,4,6,7) = \pm\Phi_{K\cup 5}^{\{A,C\},\{B\},\{E\}}\Phi_{K\cup\{5,7\}/7}^{\{A,B\},\{C\}} $$

$= \pm$ 
From the pictures we can read off the contractions and deletions of edge 5 and deduce that the reduction with respect to edge 5 is

$$ {}^{7}\Psi_{G'}(1,2,3,4,5,6,7) $$
$$ = \pm\left(\Phi_{K}^{\{A,C\},\{B\}}\Phi_{K}^{\{A,B\},\{C\},\{D\}} - \Phi_{K}^{\{A,C\},\{B\},\{D\}}\Phi_{K}^{\{A,B\},\{C\}}\right) $$

But this is itself a five-invariant, ${}^{5}\Psi_{G}(1,2,3,4,5)$, expanded as

$$ \Psi_{G}^{145,235}\Psi_{G,5}^{12,34} - \Psi_{G,5}^{14,23}\Psi_{G}^{125,345} $$

where G is as in the previous proposition. Applying Proposition 33 to rewrite this 5-invariant completes the proof. □

Theorem 35. *Let G and G' be obtained, as above, by splitting a triangle. Suppose that G' is linearly reducible with respect to a set of edges $\{1,\dots,7\}\cup S$ (in that order), where $S\subset G'\backslash\{1,\dots,7\}$. Then G is linearly reducible with respect to $\{1,\dots,5\}\cup S$ and has a weight drop if and only if G' has a weight drop.*

Proof. It follows from the two previous propositions that:

$$ {}^{5}\Psi_{G}(1,2,3,4,5) = \pm{}^{7}\Psi_{G'}(1,2,3,4,5,6,7)\ . $$

□

Note that G' is always linearly reducible with respect to $\{1,2,3,4,5,6,7\}$ (the case $S=\emptyset$), because every 5-edge minor of G' has either a triangle or a 3-valent vertex, and so G' contains no non-trivial 5-invariants.

By deleting edges 6 and 7 in G' we get a special case of the double triangle where a single triangle with two three-valent vertices is contracted to two three-valent vertices connected by an edge. If we also consider the two remaining edges adjacent to B, then by similar arguments 7 and 5 integrations respectively give the same denominator. By deleting edge 4 we get a special case with a three-valent vertex in the double triangle contracting to a single triangle with a three-valent

vertex. If we also consider one more edge adjacent to C then by similar arguments 7 and 5 integrations respectively again give the same denominator.

4.5. **Families of weight drop graphs.** The first family of weight drop graphs is already well known.

Proposition 36. *Let G be two vertex reducible. Then G has a weight drop.*

Proof. Write G as the 2-vertex join of two graphs G_1 and G_2. Number the edges of G in any way so that edges $1, 2$ lie in G_1 and edges $3, 4$ lie in G_2. Then by Proposition 21, $\Psi_G^{12,34} = 0$ and $\Psi_G^{13,24} = \Psi_G^{14,23}$. At the fourth stage of integration (I_G^4 above) the denominator reduces to

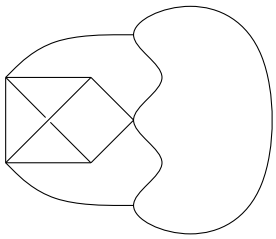
$$\Psi_G^{13,24}\Psi_G^{14,23} = (\Psi_G^{13,24})^2 \ .$$

Thus we have a weight drop. □

The same argument shows that any graph with a double edge and more than 4 edges in total has weight drop.

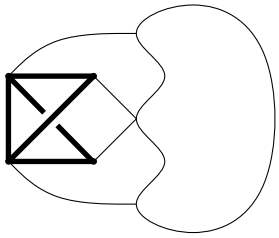
The first family of weight drop graphs which goes beyond 2-vertex reducible graphs was observed empirically by one of us (KY) and independently by Oliver Schnetz, who later also found a proof. The most beautiful proof, also observed by Oliver Schnetz, is in terms of the material of this section.

Example 37. Every graph of the form

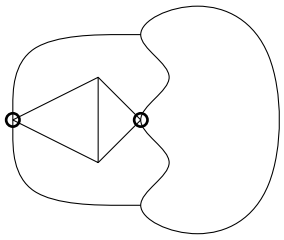


has a weight drop.

To see this consider the pair of triangles marked below by heavy edges



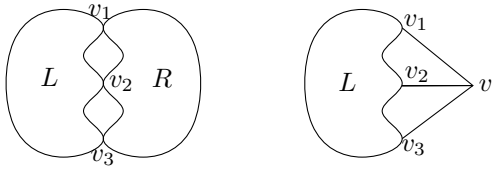
By Theorem 35 this graph has weight drop iff



does. The latter is two vertex reducible at the marked vertices and hence by Proposition 36 has weight drop.

Further families can be built along these lines by repeated double triangles. To make a more systematic search for weight preserving operations and weight drop families we can use the 3-vertex join result as in the next section.

4.6. **Operations on 3-connected graphs.** Let G be a 3-connected graph. We can write $G = L \cup_3 R$ as the join of two graphs L and R along three distinguished vertices v_1, v_2, v_3 (below left). By Theorem 23 there is a universal formula for the graph polynomial of G in terms of Dodgson polynomials. Thus for any fixed left-hand side L, we can consider the graph $\widetilde{L}$ obtained by joining a vertex v to v_1, v_2, v_3 (right):



Suppose that L has at least 5 edges, and let x, y, z denote the Schwinger parameters of the edges $\{v, v_1\}, \{v, v_2\}, \{v, v_3\}$ respectively. Suppose that $\widetilde{L}$ is denominator reducible. Then we define

$$\rho_L(x, y, z) = {}^{e_L}\Psi_{\widetilde{L}}(\alpha_1, \ldots, \alpha_{e_L}) \in \mathbb{Q}[x, y, z]$$

where the edges of L are numbered $1, \ldots, e_L$. By Theorem 23, the polynomial ρ_L computes the general shape of the denominator reduction of any graph $G = L \cup_3 R$ after reducing out all the edges in L.

Proposition 38. *Suppose that G is the 3-vertex join of L and R. Let*

$$x_R = \Phi_R^{\{1\},\{2,3\}} \ , \ y_R = \Phi_R^{\{2\},\{1,3\}} \ , \ z_R = \Phi_R^{\{1,2\},\{3\}} \ .$$

We have shown that $x_R y_R + x_R z_R + y_R z_R = \Psi_R \Phi_R^{\{1,2,3\}}$ (Proposition 22), and

$$x_R + y_R = \Psi^3_{\widetilde{R},12} \ , \ x_R + z_R = \Psi^2_{\widetilde{R},13} \ , \ y_R + z_R = \Psi^1_{\widetilde{R},23} \ .$$

If G is denominator reducible, then Theorem 23 implies that:

$$ {}^{e_L}\Psi_G(\alpha_1, \ldots, \alpha_{e_L}) = (\Psi_R)^{2-\deg \rho_L} \rho_L(x_R, y_R, z_R) \ . $$

It follows in particular that if ρ_L is of degree 0 or is a perfect square, then G has a weight drop.

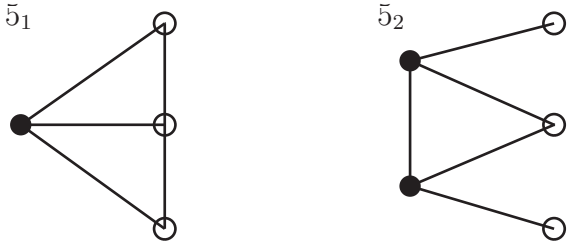
There are a limited number of possibilities for the polynomials ρ_L. This gives rise to families of weight-preserving operations as follows.

Corollary 39. *Suppose that $\rho_{L_1} = \rho_{L_2}$, and let $G = L_1 \cup_3 R$ and $G_2 = L_2 \cup_3 R$ for any R. Then the denominator reductions of G_1 and G_2 are the same after reducing out all the edges in L_1 and L_2:*

$$ {}^{e_{L_1}}\Psi_{G_1}(\alpha_1, \ldots, \alpha_{e_{L_1}}) = {}^{e_{L_2}}\Psi_{G_2}(\alpha_1, \ldots, \alpha_{e_{L_2}}) \ . $$

Thus G_1 has a weight drop after reducing with respect to the edges $E(L_1) \cup S$, where $S \subset E(R)$, if and only if G_2 has a weight drop after reducing with respect to $E(L_2) \cup S$.

We begin a classification of graphs L and compute their polynomials ρ_L as follows. In the following diagrams, the white vertices are v_1, v_2, v_3 from top to bottom, and the polynomials ρ_L are indicated underneath. At 5 edges, there are only two possibilities for L which have neither a double edge nor a two-valent vertex (these are the simple 5-local minors in the terminology of [2]):



$y(xy + xz + yz)$ $\qquad$ y

Note that graphs 5_1 and 5_2 have a split triangle (resp. split 3-valent vertex), so if they occur in a graph, we can, as noted after Theorem 35, reduce to a smaller graph, except in trivial cases where the extra edges are not available. At 6 edges, there are exactly six such 6-local minors:

6_1 
$(xy + yz + xz)^2$

6_2 
$xy + yz + xz$

6_3 
xz

6_4 
$(x + y)y$

6_5 
xz

6_6 
1

The graphs 6_1 and 6_6 have weight drops, and we obtain the first identity: $\rho_{6_3} = \rho_{6_5}$. However, most of the above graphs (except for 6_2 and 6_6) contain a double-triangle or split 3-vertex and do not tell us anything new. From now on, we only consider graphs which do not contain a double triangle, rather than giving the complete list. It turns out that at 7 edges, we obtain polynomials ρ_L which have already appeared above, except for the following graph:

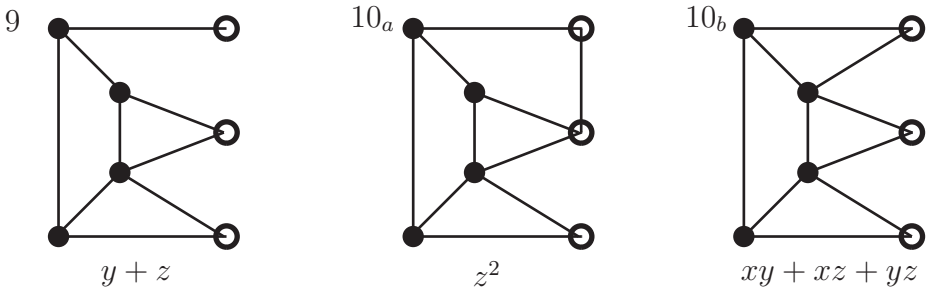
7 
$(x + y)(xy + xz + yz)$

Similarly, at 8 edges, we get a new identity for the graphs:

8_a 
$y(x + z)$

8_b 
$y(x + z)$

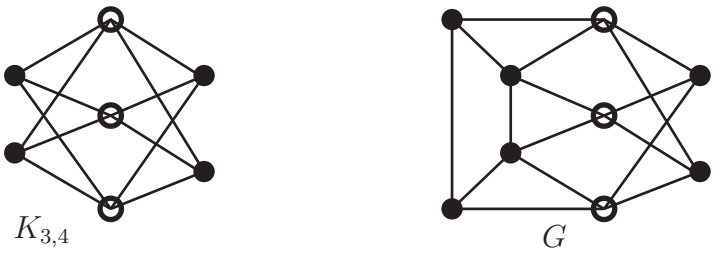
neither of which is amenable to a double-triangle type reduction. We conclude that $\rho_{8_a} = \rho_{8_b}$. We conclude with a few more examples to illustrate the general principle:



Thus ρ_{10_a} has weight drop, and we get an identity $\rho_{10_b} = \rho_{6_2}$. One can continue generating larger and larger graphs L (provided they are denominator-reducible) and compute their polynomials ρ_L, giving rise to more and more complicated identities of the form $\rho_{L_1} = \rho_{L_2}$.

4.7. **Examples of 3-connected operations.** The previous discussion enables one to prove results about graphs which are inaccessible by double-triangle type arguments.

Corollary 40. *The following graphs have a weight drop:*



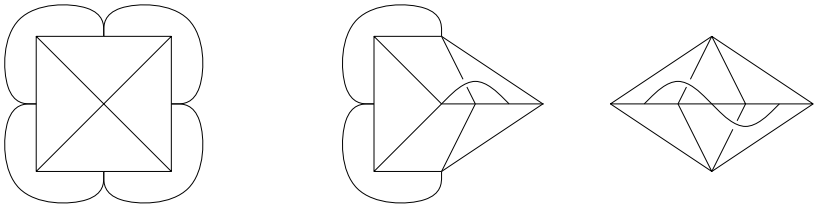
The same result holds more generally for $K_{3,4} \cup_3 R$ or $G \cup_3 R$ where R is any 3-vertex reducible graph connected to the 3 white vertices.

Proof. The graph $K_{3,4} = 6_2 \cup_3 6_2$ on the left is denominator reducible and has a weight drop by direct calculation [2]. Since $\rho_{10_b} = \rho_{6_2}$ it follows that $G = 10_b \cup_3 6_2$ also has a weight drop by Corollary 39. The last statement follows from a similar argument, after noting (again by direct computation) that $\rho_{\widetilde{K_{3,4}}} = 0$. □

Now we can consider the graphs obtained by gluing 8_a and 8_b together. There are three possibilities which preserve the symmetries of

the ρ polynomials: $8_a \cup 8_a$, $8_a \cup 8_b$, $8_b \cup 8_b$

(4)



$8_a \cup 8_a$ $8_a \cup 8_b$ $8_b \cup 8_b$

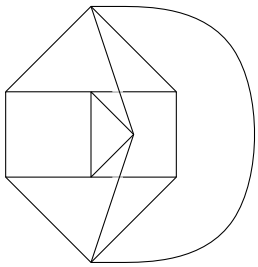
Arguing as above we conclude that all 3 have the same weight.

Remark 41. *It is known that two graphs G_1, G_2, which, when completed by adjoining a new vertex to all 3-valent vertices give rise to the same graph, necessarily have the same period. O. Schnetz has shown this nicely in* [4]. *In particular, they have the same weight. This should imply that G_1 has a weight drop in the denominator sense if and only if G_2 does. Can one find a combinatorial proof of this fact?*

Remark 42. *We obtained a list of 3-vertex connected operations on graphs simply by calculating their universal polynomials ρ. Is it possible to do the same for graphs with higher degrees of vertex connectivity? In other words, for every $n \geq 3$, is there a finite list of 'right-hand sides' $R_1, \ldots, R_{N_n}$ such that if a property holds for all $L \cup_n R_i$ for $1 \leq i \leq N_n$ then it holds for all graphs $L \cup_n R$? In the 3-vertex connected case we have shown that $N_3 = 1$. It would be interesting to draw up a list of 4-vertex connected weight-preserving operations, of which the triangle splitting operation is one example.*

The results above are almost sufficient to explain all known weight-drops. Of the graphs up to 8 loops which have been calculated to be weight drop, the application of Theorem 35 and Proposition 36 without any further identities explains all but seven of the graphs. One of these can be explained immediately by planar duality. Two more of them are $K_{3,4}$ and G from Corollary 40. Three more are the graphs of (4) which all must have the same weight. The remaining graph is

(5)



So the methods of this paper suffice to prove all known weight drops except for two. Fortunately, these graphs are amenable to the denominator reduction algorithm. Alternately, if we further allow ourselves Schnetz' completion and twist operations, which preserve the period [4], but which are not understood in this language of graph polynomials, then the graphs of (5) and (4) must all have the same value as G from Corollary 40, giving weight drop for all of them.
